DfE Best Practice for R :: CHEAT SHEET

DfE-R COMMUNITY

Software

Write code in the **RStudio** IDE

Use **git** to version-control your code and analysis

(or) Use **GitHub** / **AZURE DevOps** to collaborate with other people
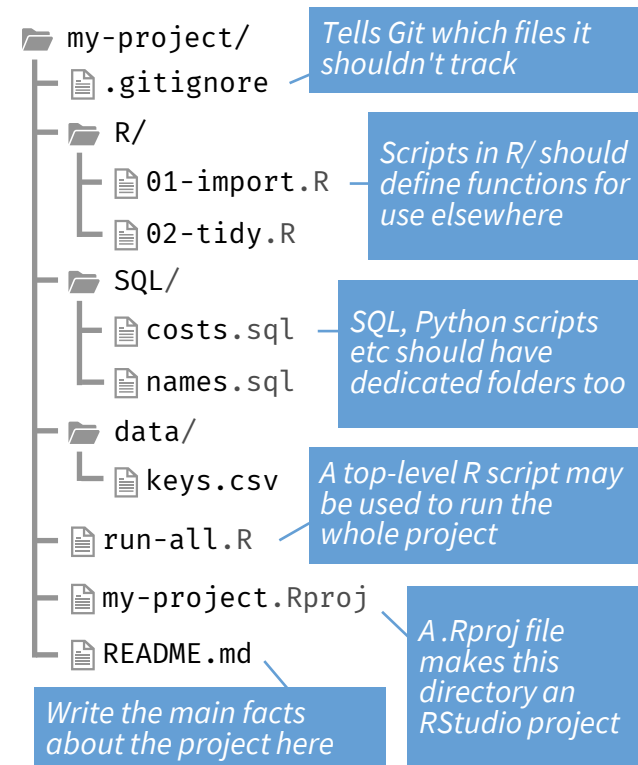

Projects

PROJECT CREATION

- **Create** a new project in RStudio using `File > New Project > New Directory`
- **Do** put projects in `C:\Users\your-name\Documents`
- **Don't** put projects in `C:\Users\your-name\OneDrive - Department for Education\Documents`

PROJECT STRUCTURE

Projects are folders containing a file with the extension .Rproj. Projects should be structured something like this:

```
📁 my-project/
├── 📄 .gitignore          Tells Git which files it shouldn't track
├── 📁 R/
│   ├── 📄 01-import.R      Scripts in R/ should define functions for use elsewhere
│   └── 📄 02-tidy.R
├── 📁 SQL/
│   ├── 📄 costs.sql        SQL, Python scripts etc should have dedicated folders too
│   └── 📄 names.sql
├── 📁 data/
│   └── 📄 keys.csv
├── 📄 run-all.R           A top-level R script may be used to run the whole project
├── 📄 my-project.Rproj    A .Rproj file makes this directory an RStudio project
└── 📄 README.md           Write the main facts about the project here
```

NB, `usethis::use_description()` + `usethis::use_namespace()` will turn this structure into a package!

Packages

Packages should be loaded in one place with successive calls to `library()`

Use the **tidyverse** for normal wrangling, plotting etc

Use **tidymodels** for modelling and machine learning

Use {**shiny**}, {**bslib**} and {**bs4Dash**} for app development

Use **r-lib** packages like {**rlang**}, {**cli**} and {**glue**} for low-level programming

GitHub stars are a good proxy for a package's quality. Not sure whether to use a package? If it has >200 stars on GitHub it's probably okay!

Getting Help

CREATE A REPREX

- A **minimal, reproducible example** should demonstrate the issue as simply as possible
- Copy your example code and run **reprex::reprex()** to embed errors/messages/outputs as comments
- Use your reprex in a question on Teams or Stackoverflow

```
print("Hello " + "world!")
#> Error in "Hello " + "world!": non-
numeric argument to binary operator
```

↖ This reprex minimally demonstrates an error when attempting to use + for Python-style string concatenation

ETIQUETTE WHEN ASKING QUESTIONS

Don't	Do
Post screenshots of your code	Use **reprex::reprex()** and paste your code as text
Include big files	Use **dput()** or **tibble::tribble()** to include a data sample
Ignore messages or warnings	**Ensure your code only fails where you're expecting it to**

Databases

- Use {**DBI**} and {**odbc**} to connect to SQL
- Use **helper functions** to create connections

```
connect_to_db <- function(db) {
  DBI::dbConnect(
    odbc::odbc(), Database = db,
    # Hard-code common options here
  )
}
        # Connect using the helper
        con <- connect_to_db("DWH_PL")
```

Functions

- Write functions to **reduce repetition** or **increase clarity**
- Write many **small** functions that **call each other**
- Define functions in **dedicated scripts** with corresponding names

NAMING CONVENTIONS

✓ Good (verb-like)	✗ Bad (noun-like)
compute_totals()	totals_getter()
fit_model()	modeller_func()
import_datasets()	project_data()

Styling

For other styling guidance, refer to the Tidyverse style guide

NAMING THINGS

- Use **lower_snake_case** *for most objects* (functions, variables etc)
- **Title_Snake_Case** may be used for *column names*
- Use only **syntactic** names where possible (include only *numbers*, *letters*, *underscores* and *periods*, and don't start with a number)

WHITESPACE

- **Add spaces** after commas and around operators like |>, %>%, +, -, *, /, = and <-
- **Indentation increases** should always be by *exactly* 2 spaces
- **Add linebreaks** when lines get longer than **80** characters.
- When there are many arguments in a call, **give each argument its own line** (including the first one!)

WRITING FUNCTIONS: WORKFLOW

```
a <- complex operation on a
b <- complex operation on b
c <- complex operation on c
d <- complex operation on d
```
1. Repetitive, complex code; purpose clarified by comments

```
operate_on <- function(x) {
  complex operation on x
}
```
2. Complex logic abstracted into functions

```
a <- operate_on(a)
b <- operate_on(b)
c <- operate_on(c)
d <- operate_on(d)
```
3. Repetition reduced; clearer code; less need for comments

```
# Good (lower_snake_case everywhere):
add1          <- function(x) x + 1
first_letters <- letters[1:3]
iris_sample   <- slice_sample(iris, n = 5)

# Bad (non-syntactic, not lower_snake_case):
`add 1`       <- function(x) x + 1
FirstLetters  <- letters[1:3]
iris.sample   <- slice_sample(iris, n = 5)
```

```
# Good (lots of spaces, indents always by +2):
df <- iris |>
  mutate(
    Sepal.Area = Sepal.Width * Sepal.Length,
    Petal.Area = Petal.Width * Petal.Length
  )

# Bad (inconsistent spacing and indentation):
df<-iris |>
  mutate(Sepal.Area=Sepal.Width*Sepal.Length,
    Petal.Area=Petal.Width*Petal.Length)
```

Learning More

- Common data science tasks: use *R for Data Science (2e)*
- Developing packages: use *R Packages (2e)*
- Advanced programming: use *Advanced R (2e)*
- Developing apps: use *Mastering Shiny*
